Transpose (rotate) data from rows to columns or vice versa

Transposing data is the process of switching data from rows to columns or vice versa. This is often done to make the data easier to read or to improve the layout of a spreadsheet.

How to Transpose Data in Excel

There are two main ways to transpose data in Excel:

Using the Paste Special Feature:

- [Video: Transpose \(rotate\) data from rows to columns or vice versa - Microsoft 365](#)
 - [Download a sample data workbook #1](#)

Tips: The shortcut key for Paste Special is **CTRL+ALT+V**.

Using the TRANSPOSE Function:

Flash Fill in Excel

Flash Fill is a feature in Excel that automatically fills in data based on patterns it recognizes in your existing data. It is a powerful tool that can save you a lot of time and effort, especially when working with large datasets.

Tips: 'CTRL+E' is the shortcut for Flash Fill.

Here are some examples of how to use Flash Fill:

Extracting data from text: For example, suppose you have a column of text that contains email addresses. You can use Flash Fill to extract the email addresses from the text and put them in a separate column.

Combining text from multiple columns: For example, suppose you have a list of first names in one column and a list of last names in another column. You can use Flash Fill to combine the first and last names into a single column.

Define and use names in formulas

By using names, you can make your formulas much easier to understand and maintain. You can define a name for a cell range, function, constant, or table.^[^1]

Formulas with cell references can be difficult to understand, especially for complex calculations. Using names for cell ranges or tables makes them much easier to understand, especially for others using your workbook.
