Classes

- Classes act as blueprints for creating objects.

What are instance attributes?:

- Unique to each instance (object) of a class.
- Store data specific to that object.
- Defined within the **init()** constructor method, using the self parameter.

Example #:

```
# Class Definition
class Student:
    # Constructor
    def __init__(self, name, age, grade): # self refers to the current object
being created.
        self.name = name
        self.age = age
        self.grade = grade
    # Method
    def info(self):
        print(f"Name = {self.name} Age = {self.age} Grade = {self.grade}")

# Object Creation

student1 = Student("Hamza", 8, 3)
student2 = Student("Muhammad", 15, 10)

# Accessing Attributes and Methods

print(student1.name)
```

```
student1.info()
student2.info()
```

Key Points:

- Classes act as blueprints for creating objects.
- Objects are instances of classes, each with their own attributes (data) and methods (behaviors).
- The `__init__()` method initializes objects when they're created.
- Methods are functions defined within a class that operate on the object's data.
- `self` is used to access the object's attributes and methods within its methods.

Example #:

```
class Student:
    """Represents a student with their name, age, and grade."""

    def __init__(self, name, age, grade):
        """Initializes a Student object with the given attributes."""
        self.name = name
        self.age = age
        self.grade = grade

    def get_name(self):
        """Returns the student's name."""
        return self.name

    def get_age(self):
        """Returns the student's age."""
        return self.age

    def get_grade(self):
        """Returns the student's grade."""
        return self.grade

    def set_grade(self, new_grade):
        """Updates the student's grade."""
        self.grade = new_grade

    def introduce(self):
        """Prints a self-introduction message."""
        print("Hello, my name is", self.name, "and I'm in grade", self.grade)

# Example usage
student1 = Student("Hamza", 8, 3)
student2 = Student("Muhammad", 16, 10)

student1.introduce() # Output: Hello, my name is Alice and I'm in grade 9
print(student2.get_name()) # Output: Bob
student2.set_grade(11)
print(student2.get_grade()) # Output: 11
```
